Crab nebula

Galactic Center

The Extreme Non-Thermal Universe: CDY Initiative

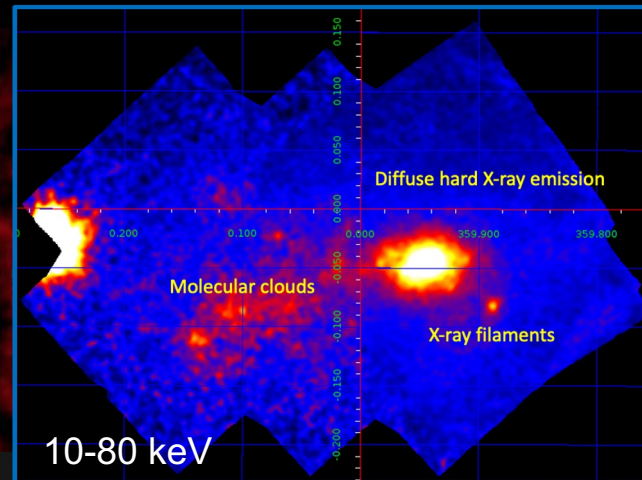

WORKING TOGETHER TO UNDERSTAND THE SITES OF EXTREME ACCELERATION...

Outline of the talk

-
- I will talk mostly about non-thermal, diffuse X-ray sources associated with Galactic TeV sources.
 - I will NOT talk about (1) accreting objects, (2) transients, (3) extragalactic sources, or (4) thermal X-ray emission.
 - Overview of NuSTAR telescope and observations (10 min)
 - NuSTAR observations of Galactic TeV sources (30 min)
 - Supernova remnants
 - Pulsar wind nebulae
 - Other TeV sources
 - Galactic Center
 - Future X-ray probe mission in the 2030s (5 min)

NuSTAR X-ray telescope

X-ray telescopes in the 2020s

- **Chandra, XMM, NuSTAR most utilized for observing diffuse X-ray emission**
- Swift, NICER and MAXI: X-ray transients
- IXPE: X-ray polarization (launched in December 2021)
- eROSITA: all-sky survey (currently suspending science operation)
- XRISM: high-resolution X-ray spectroscopy (FY 2023 launch)

NuSTAR: bringing the high energy Universe into focus

NASA Study Helps Explain Limit-Breaking Ultra-Luminous X-Ray Sources
Apr 6, 2023 • News Release

In a recent study published in The Astrophysical Journal, researchers report a first-of-its-kind measurement of a ULX taken with NASA's Nuclear Spectroscopic Telescope Array (NuSTAR). The finding confirms that these light emitters are indeed as bright as they seem and that they break the Eddington limit.

NuSTAR Celebrates 10 Years of Operations
Artwork • Jun 9, 2022

After a decade of operation, NuSTAR continues to open new horizons, discover fascinating objects, and expand our knowledge of the Universe.

Black Hole Tidal Disruption Event

NuSTAR: the first focusing X-ray telescope operating above 10 keV

- PI: Fiona Harrison
- Optics built at Columbia U (Lead: Chuck Hailey)
- Detectors developed at CalTech

NuSTAR's effective area compared to other x-ray satellites.

| | |
|--------------------------------------|--|
| Energy Band | 3 - 79 keV |
| Angular Resolution | 58" (HPD), 18" (FWHM) |
| Focal Plane Size | 12' x 12' |
| Energy Resolution | 0.4 keV at 6 keV, 0.9 keV at 60 keV (FWHM) |
| Temporal Resolution | 0.1 msec |
| Maximum Flux Measurement Rate | 10,000 cts/s |
| ToO response | < 24 hours |

11 years of NuSTAR operation

- NASA SMEX mission launched in June 2012
- Year 1-2: PI-led primary mission including the Galactic Center survey and young SNRs
- Year 3-5: Legacy program including Galactic TeV sources
- Year 3 and later: GO program
- More ToOs => time-domain astrophysics
- More Joint observations with other telescopes => multi-messenger astrophysics
- More Large GO programs (> 500 ks) => high-risk, high-return science

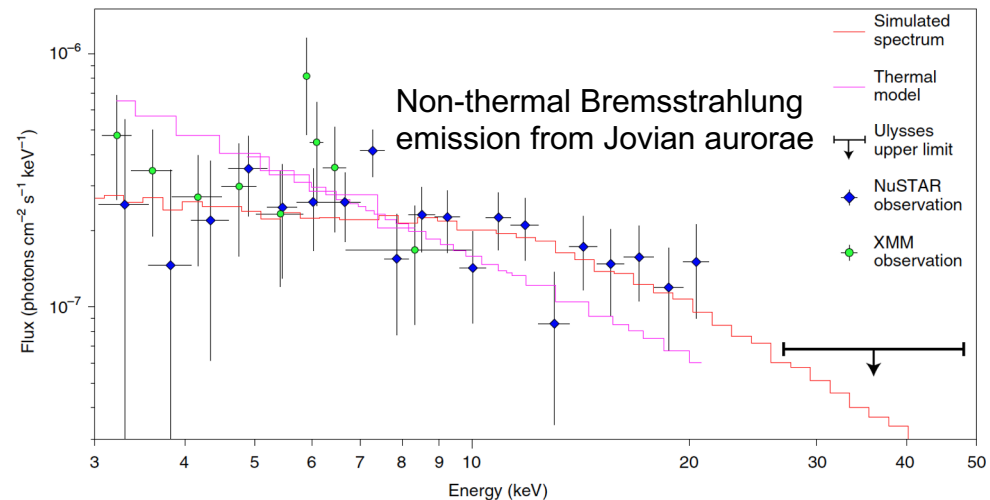

NuSTAR is an excellent non-thermal X-ray emission detector

- Many X-ray sources show thermal emission ($kT \sim 0.1$ to few keV)
 - X-ray binaries
 - Neutron stars
 - Cataclysmic variables
 - SNRs
 - Star clusters
 - Diffuse X-ray emission
 - Jupiter (!)
- $E > 10$ keV (unique to NuSTAR) for detecting and characterizing non-thermal X-ray emission *cleanly*.

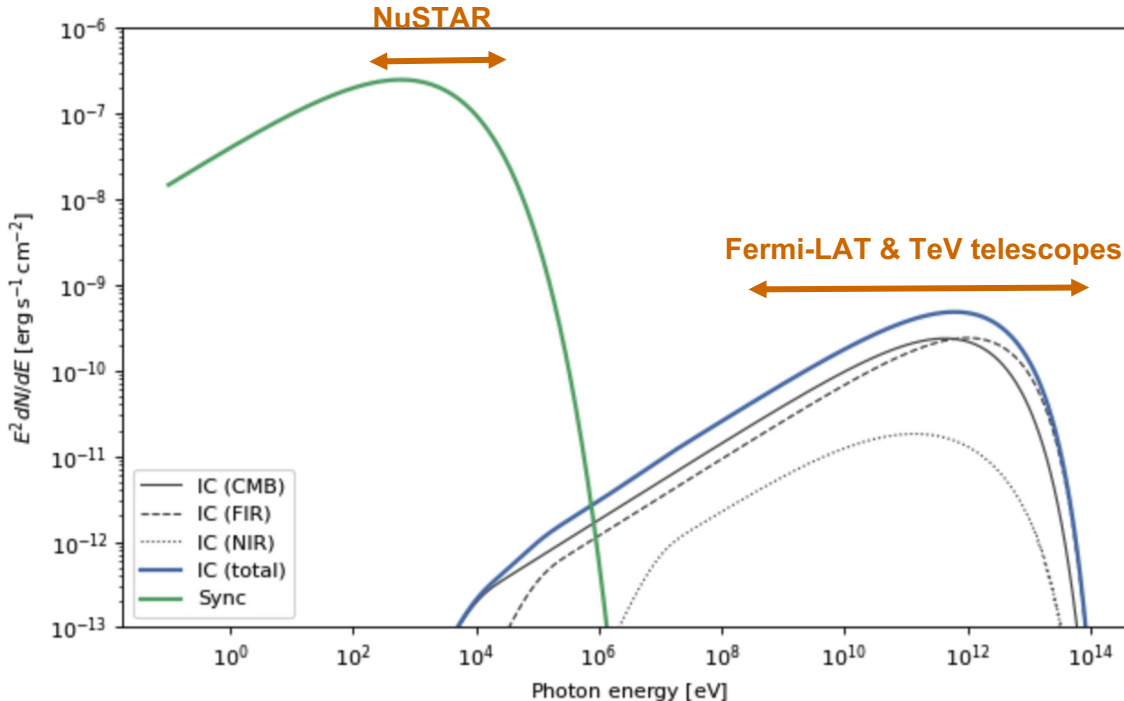

NuSTAR uniquely explores synchrotron radiation from TeV-PeV electrons

- Energetic particle accelerators produce TeV-PeV electrons
 - Primary electrons (leptonic accelerators like PWNe)
 - Secondary electrons from p-p collisions (hadronic accelerators)
- Hard X-ray band (> 10 keV)
 - $E_{\text{syn}} = 40 \text{ keV} (E_e/100 \text{ TeV})^2 (B/0.1 \text{ mG}) \Rightarrow$ Sensitive to $E_{\text{max},e}$
 - $t_{\text{syn}} = 1.2 \text{ yr} (B/0.1 \text{ mG})^{-3/2} (E_{\text{syn}}/10 \text{ keV})^{-1/2} \Rightarrow$ Faster cooling/variability

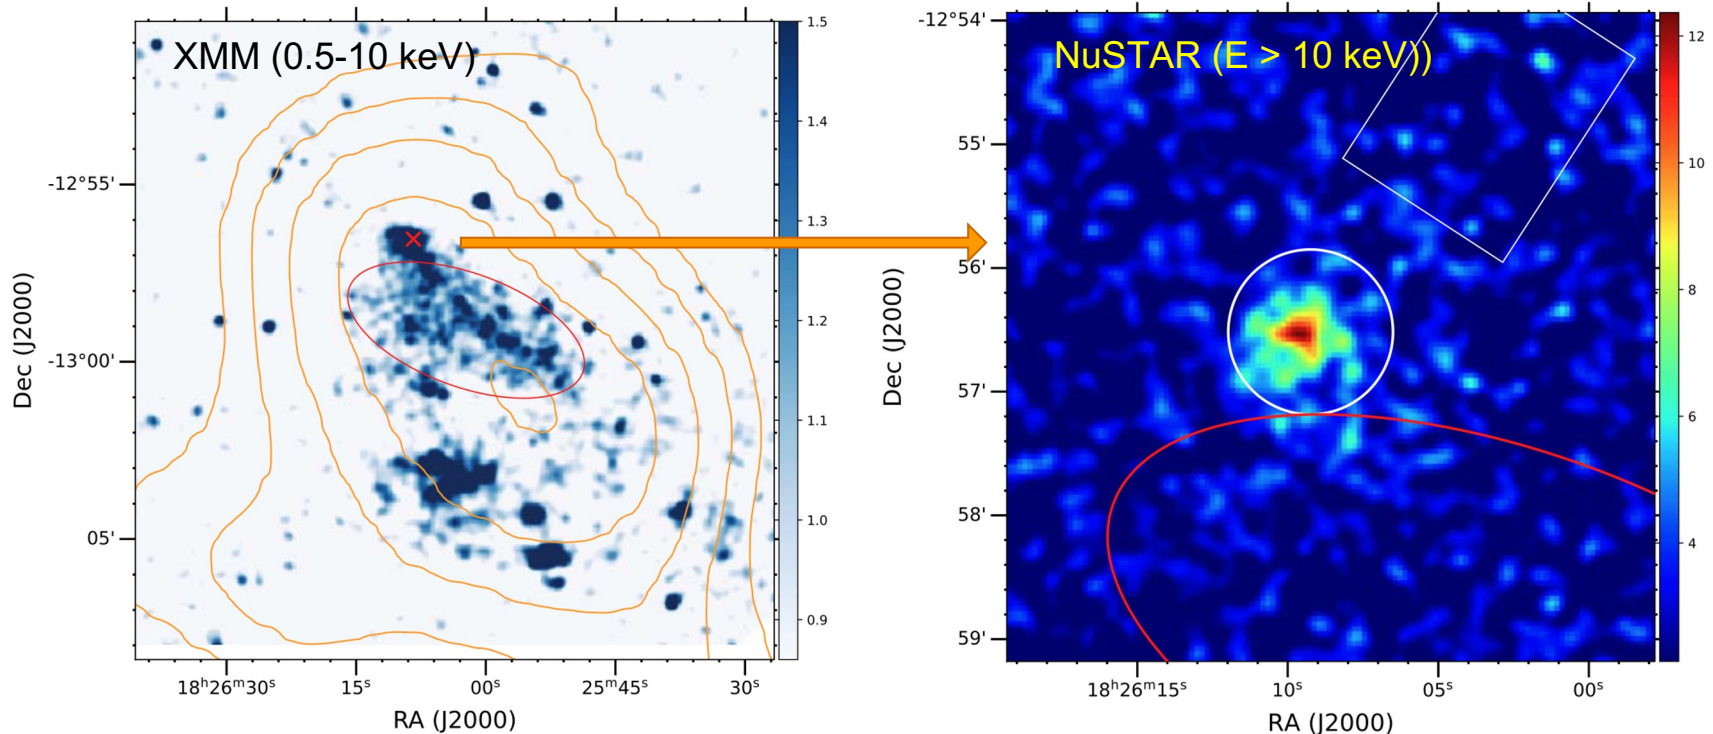

Example SED model from NAIMA website

A conventional strategy to explore Galactic TeV sources in the X-ray band

- Many Galactic TeV sources are extended, not well localized or have multiple counterpart candidates
- XMM survey with large FOV (or eROSITA) in the soft X-ray band
- NuSTAR follow-up, pinpoint observations for non-thermal X-ray spectroscopy and morphology

HESS J1826-130 = Eel PWN (Burgess+ 22)

NuSTAR legacy program in 2017-18: 3 Galactic TeV sources

- NuSTAR legacy program => high-risk, long-exposure observations
 - Started with NuSTAR-VERITAS-HAWC collaboration
 - Our collaboration evolved into a large group of 40 members from NuSTAR, XMM, Chandra, XRISM, VERITAS, HAWC, Fermi, ICECUBE.
 - More X-ray observations proposed, approved and performed until now
- We observed 3 Galactic TeV sources
 - 1) PWN DA 495 (Coerver+ 2019)
 - 2) TeV gamma-ray binary HESS J0632+057 with VERITAS (Archer+ 2020)
 - 3) Unidentified HAWC source 2HWC J1928+178 (Mori+ 2020)

NuSTAR legacy TeV source program as a bridge to GO observations

(1) DA 495 => NuSTAR large program
of observing 8 middle-aged PWNe

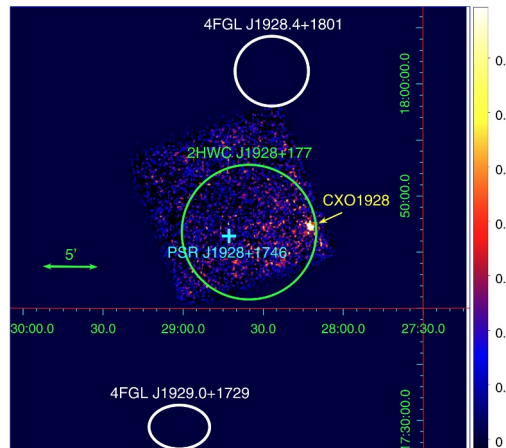

NuSTAR image (left) and SED (right) of DA 495

(2) HESS J0632+057 => NuSTAR +
VERITAS observations of other orbital

NuSTAR + VERITAS
SED data
in pre-flare phase

(3) 2HWC J1928+178 => XMM-Newton survey of
LHAASO/HAWC PeVatron sources (this year!)

NuSTAR image:
No diffuse X-ray
emission was detected

Supernova remnants

- NuSTAR observed young SNRs (Cas A, SN1987A, Tycho, Kepler, G1.9+0.3) for Ti44 line science => SN explosion mechanism
- Ti44 mapping from Cas A (Grefenstette+ 13) and detection from SN1987A (Boggs+ 15)
- Dissecting non-thermal X-ray emission from thermal emission above $E \sim 10\text{-}15$ keV
- See a systematic study of young SNRs using NuSTAR, XMM and Suzaku (Tsuji+ 21)

Tycho (Lopez+ 15)

G1.9+0.3 (Zoglauer+ 15)

Kepler (Sapienza+ 22)

Cas A: NuSTAR hard X-ray view of non-thermal X-ray emission

- NuSTAR observations in 2012-13 (2.4 Ms)
- NuSTAR paper “Locating the most energetic electrons in Cas A” (Grefenstette+15)
- Some local hard X-ray knots are detected => soft photon index ($\Gamma \sim 3$)
- Different morphology from radio and thermal X-ray emissions

Cas A: Multi-epoch Chandra observations revealed the dynamics of X-ray filaments

- Multi-epoch Chandra observations => proper motions and variabilities => V_{shock} and $B \sim 0.1\text{-}1$ mG (Sato+ 18, 23)
- However, Chandra 4-6 keV “continuum” band (where atomic lines are absent) may be still contaminated by thermal emission.
- At higher B-fields, synchrotron X-ray spectrum should get softer and fainter more quickly (possibly with a few year time-scale).

Chandra 4-6 keV “difference” image between 2000 and 2014

Synchrotron X-ray spectral evolution after 5 years (toy model)

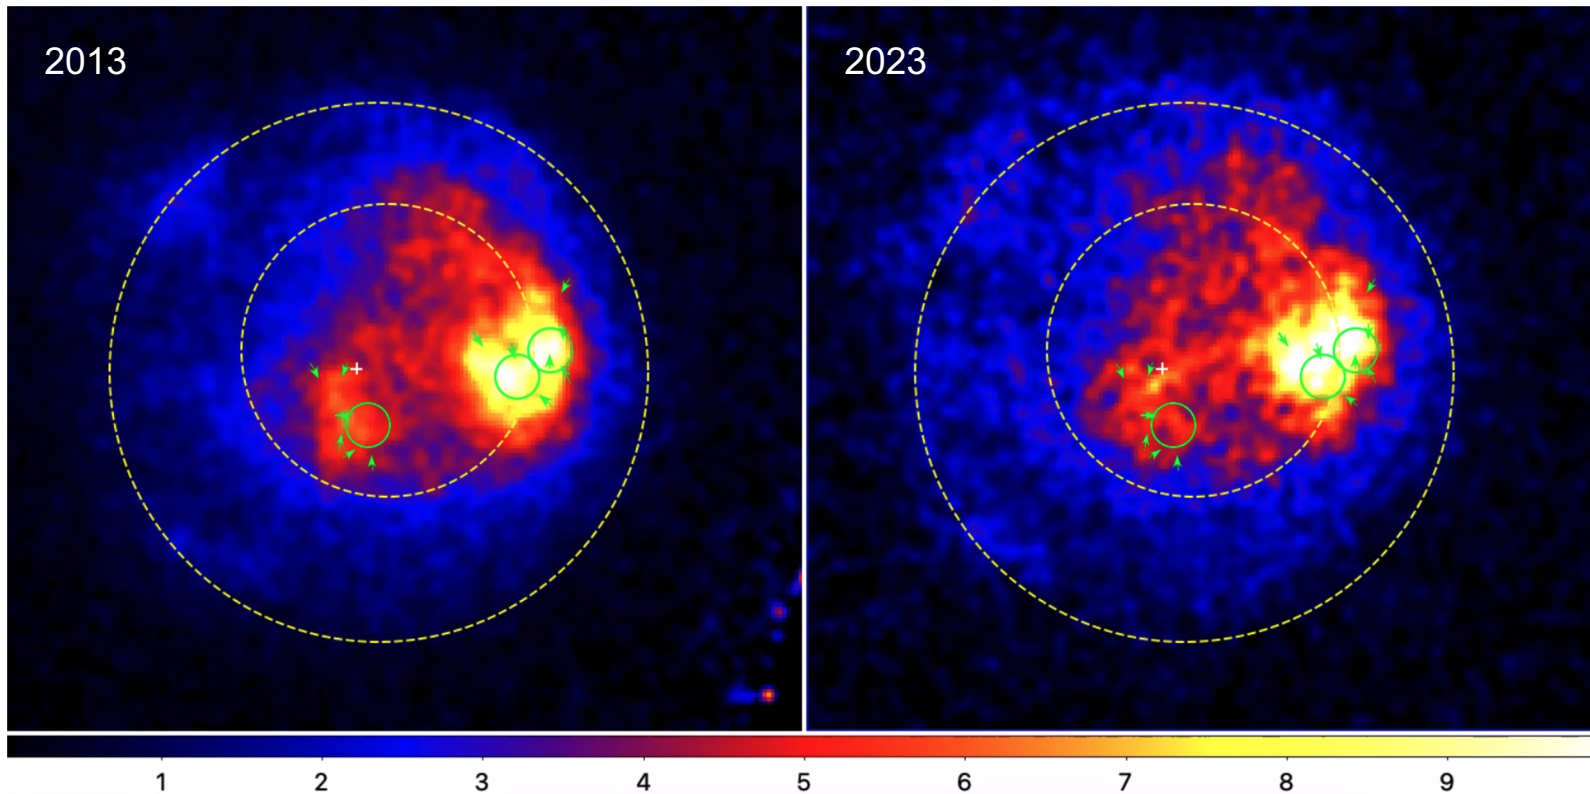

Cas A: hard X-ray knots varied over 10 yr?

- A new 200 ks NuSTAR observation in Apr 2023 (ongoing analysis by J. Woo)
- There could be some morphology changes but nothing dramatic: $B \sim 0.1$ mG?
- We are working on careful image comparison analysis for each hard X-ray knots

NuSTAR 15-50 keV flux maps (preliminary!)

Pulsar wind nebulae

- NuSTAR's timing => excise pulsar emission by phase-resolved analysis
- NuSTAR's broadband data => (1) energy-resolved morphology and (2) spatially-resolved spectroscopy
- NuSTAR detected synchrotron burnoff effects

G21.5 (NuSTAR; Nynka+ 15)

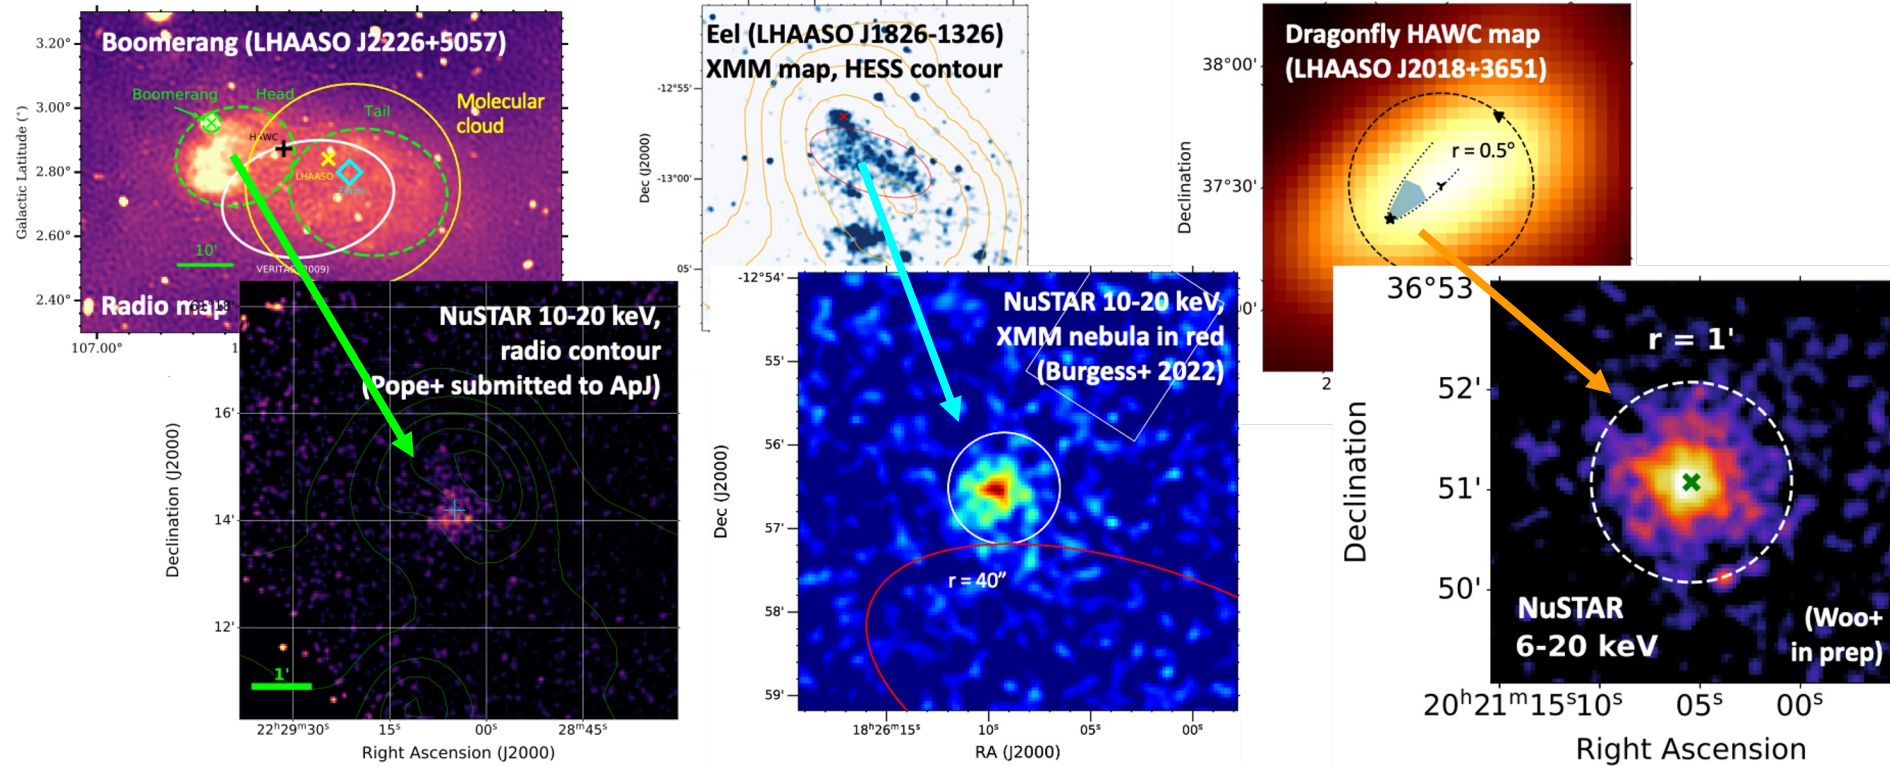

“Hand of God” MSH 15-52 (An+ 14)

- Some middle-aged PWNe ($> 10^3$ yr old) may be associated with LHAASO sources \Rightarrow Leptonic PeVatrons?
- NuSTAR detected compact hard X-ray nebulae around the pulsars

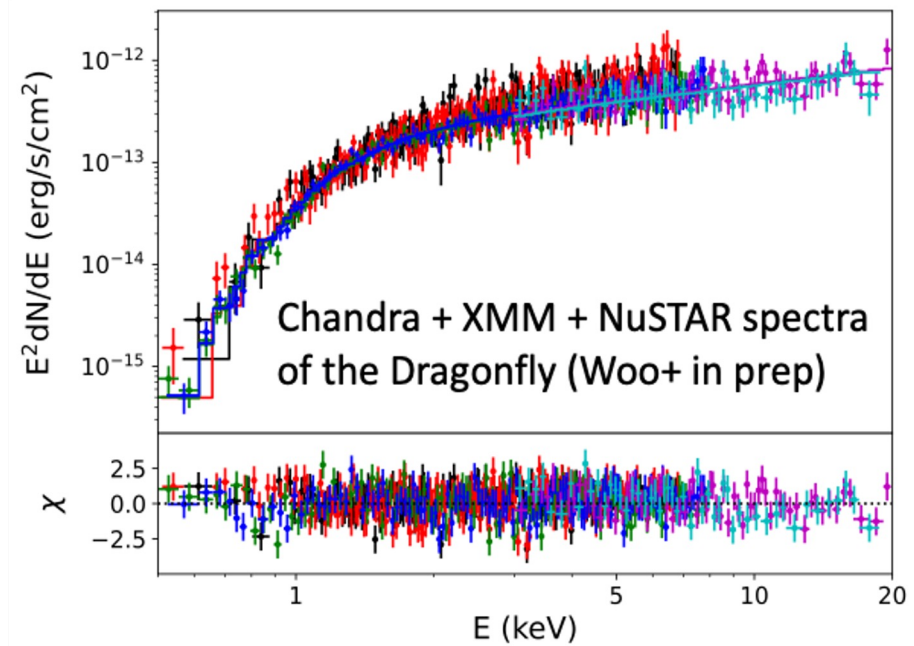

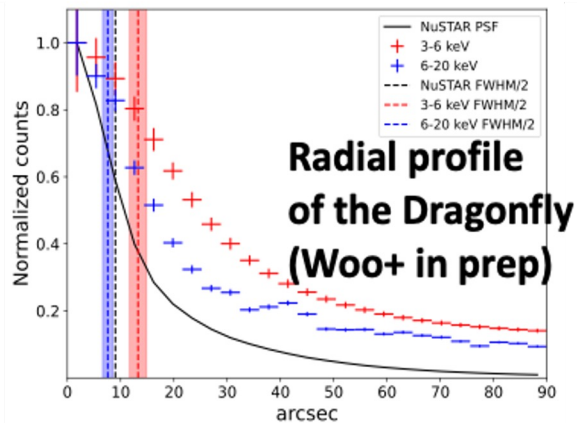

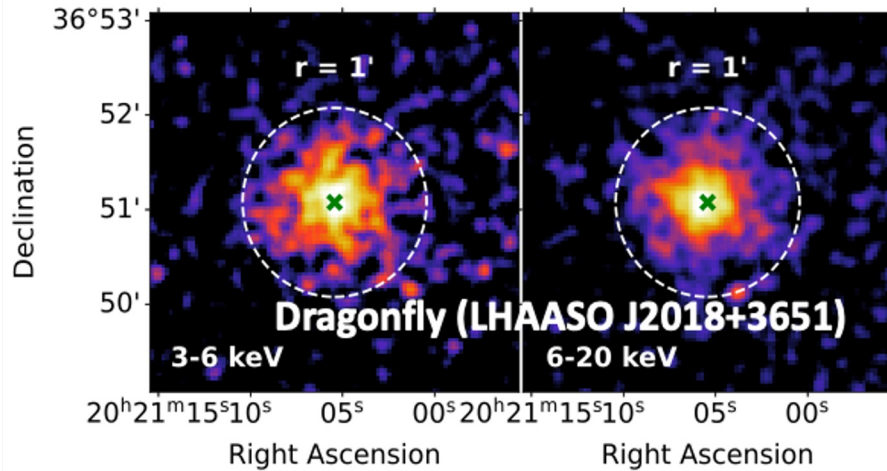

Synchrotron burnoff detected from middle-aged PWNe

- PWN size shrinking at higher energies due to faster synchrotron cooling

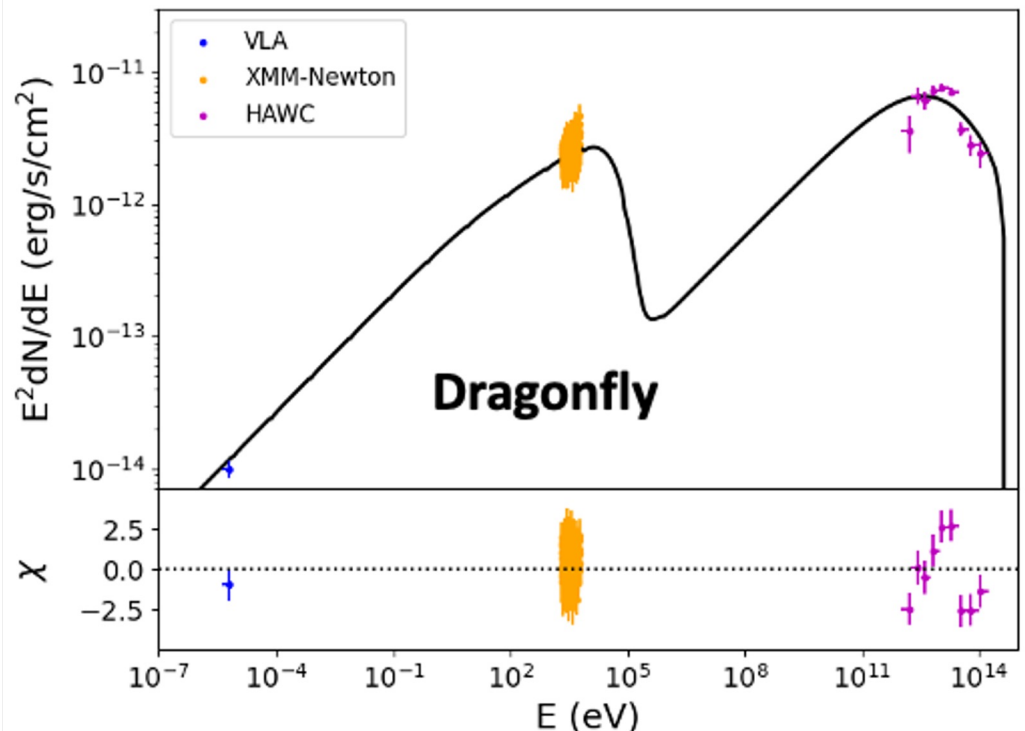

What do our results indicate about middle-aged PWN PeVatron candidates?

- Compact hard X-ray PWN with synchrotron burnoff $\Rightarrow B > 10 \mu\text{G}$ in the inner PWN
- Applying one-zone PWN time-evolution model (Gelfand+ 2008)
 - Overall B-field is low: $B \sim \text{few } \mu\text{G}$
 - $E_{\text{max}} \sim 1 \text{ PeV}$
 - PWN compression by SNR reverse shock took place
 - See another multi-zone phenomenological model approach (Park+ 22)

Other Galactic TeV sources

W50 lobes: A unique PeVatron powered by microquasar jets

- Bipolar radio jets from microquasar SS433
- HAWC discovery of TeV emission from W50 lobes (Abeysekara+ 18)
- A large X-ray survey with XMM (Safi-harb), Chandra (Tsuji) and NuSTAR (Mori)
 - XMM+NuSTAR paper on the eastern lobe (Safi-Harb+ 22)
 - XMM+NuSTAR paper on the western lobe (Mac Intyre+ in prep)
 - **NuSTAR detected hard X-ray knots ($\Gamma \sim 1.6$) in the eastern and western lobes.**

TeV gamma-ray binaries: Rare binaries not powered by accretion

- Pulsar vs stellar wind collisions => intrabinary shock (IBS)
- NuSTAR observed all 8 known TeV binaries.
- HESS J0632+057 (317-day orbital period with Be companion)
 - First observed in the NuSTAR legacy program
 - 4 joint NuSTAR and VERITAS observations performed so far
 - IBS model applied to multi-wavelength SED and lightcurve data (Kim+ 22)
 - Swift, NICER, NuSTAR and VERITAS will target the next flare in Feb'24

Mirabel 16

- Young star clusters (YSCs) are recognized as one of the primary hadronic PeVatrons.
- Some YSCs generate large-scale gamma-ray cocoons and superbubbles.
- NuSTAR observation of Westerlund 2 or HESS J1023-575 (ongoing analysis by J. Woo)
 - Non-thermal X-ray emission from colliding winds?
 - YSC detected up to 20 keV but looks faint...

Cosmic-ray profiles for the gamma-ray cocoons (Yang+ 19)

Galactic Center

- Many radio filaments => Complex magnetic field structures

Soft X-ray view of the GC (Chandra 2-8 keV)

- ~10,000 X-ray point sources and diffuse X-ray emission
- Higher concentration of X-ray sources near Sgr A*

2 deg (280 pc)

0.8 deg
(110 pc)

Chandra image of the GC region (Muno+ 09)

TeV gamma-ray view of the GC

- Two bright TeV sources
 - HESS J1745-290
 - SNR/PWN G0.9+0.1
- Extended TeV sources are correlated with molecular clouds

NuSTAR: a new hard X-ray window of the Galactic Center

- New distinct hard X-ray sources (> 10 keV) revealed by NuSTAR
 - X-ray point sources (X-ray binaries, magnetic CVs)
 - Diffuse hard X-ray emission in the central 10 pc
 - Molecular clouds
 - X-ray filaments

Belanger+ 06 (20-40 keV)
12' angular resolution (FWHM)

Mori+ 15 (10-79 keV)

X-ray filaments as a tracer of TeV-PeV electrons in the GC

- ~25 X-ray filaments (Chandra) vs ~100 radio filaments (MeerKAT)
- A few of them are likely PWNe with point sources (= pulsars)
- B-field + TeV-PeV electrons => synchrotron hard X-rays
- NuSTAR detected 4 X-ray filaments above 10 keV

Chandra image of X-ray filaments (provided by Shuo Zhang)

G0.13-0.11: PWN detected in TeV band

- Chandra revealed point source + filament morphology (Wang+ 02)
- NuSTAR detection above 10 keV (Zhang+ 20)
- Counterpart of TeV source HESS J1746-285 (HESS collab. 18)

PWN G0.9+0.1: the 2nd brightest TeV source in the GC

- One of the NuSTAR large program PWN targets
- NuSTAR detection up to 30 keV => power-law with $\Gamma \sim 2.3$
- Working on PWN SED modeling

VERITAS TeV image (Adams+ 21)

NuSTAR (10-30 keV)

NuSTAR image and spectra of G0.9+0.1 (Nynka+ in prep)

Sgr A-E knot: the brightest X-ray filament

- Not a PWN. Radio image shows magnetic field bundles.
- NuSTAR detected non-thermal emission up to 50 keV ($\Gamma = 2.3$)

Radio image of Sgr A-E knot (Morris+ 14)

NuSTAR + Chandra spectra (Zhang+ 2014)

X-ray filaments will allow us to probe CR distribution in the GC

- Where do you get TeV electrons in situ when there is no particle accelerator (e.g., PWN)?
- TeV-PeV protons travel from accelerator sites to 20 km/s cloud next to Sgr A-E knot => producing secondary electrons

GC molecular clouds emit X-rays in two different ways

- Some of the GC molecular clouds exhibit neutral Fe K α line at 6.4 keV and non-thermal X-ray continuum emission
- Two X-ray components
 - Reflection of X-ray outbursts from Sgr A* (variable)
 - Cosmic-ray bombardment (steady) => relevant to TeV emission

XMM 6.4 keV Fe K α line maps (Terrier+ 18)

Sgr B2: the most massive GC cloud

- Fe K α line and X-ray continuum decreased over ~ 20 yr (Kuznetsova+ 22, Rogers+ 22)
- Finally hit a floor of the CR-induced X-ray emission? Time to compare with TeV data?

NuSTAR images (Zhang+ 15)

Flux decreasing...

NuSTAR 20-40 keV image: the central 10 parsec

- Central hard X-ray emission (CHXE; Perez+ 15)
- Sgr A-E: X-ray filament
- MC1: molecular cloud
- SNR Sgr A East emits thermal X-rays ($kT < 5$ keV)

What is the central hard X-ray emission (a.k.a CHXE)?

- The shape and size are consistent with the nuclear star cluster
- XMM + NuSTAR spectral analysis => thermal emission ($kT \sim 35$ keV)
- Hundreds of Chandra X-ray point sources in the region (Zhu+ 18)
- Unresolved population of magnetic CVs with mean $M_{WD} \sim 0.9$ Ms (Hailey+ 16) => not relevant to GC TeV emission

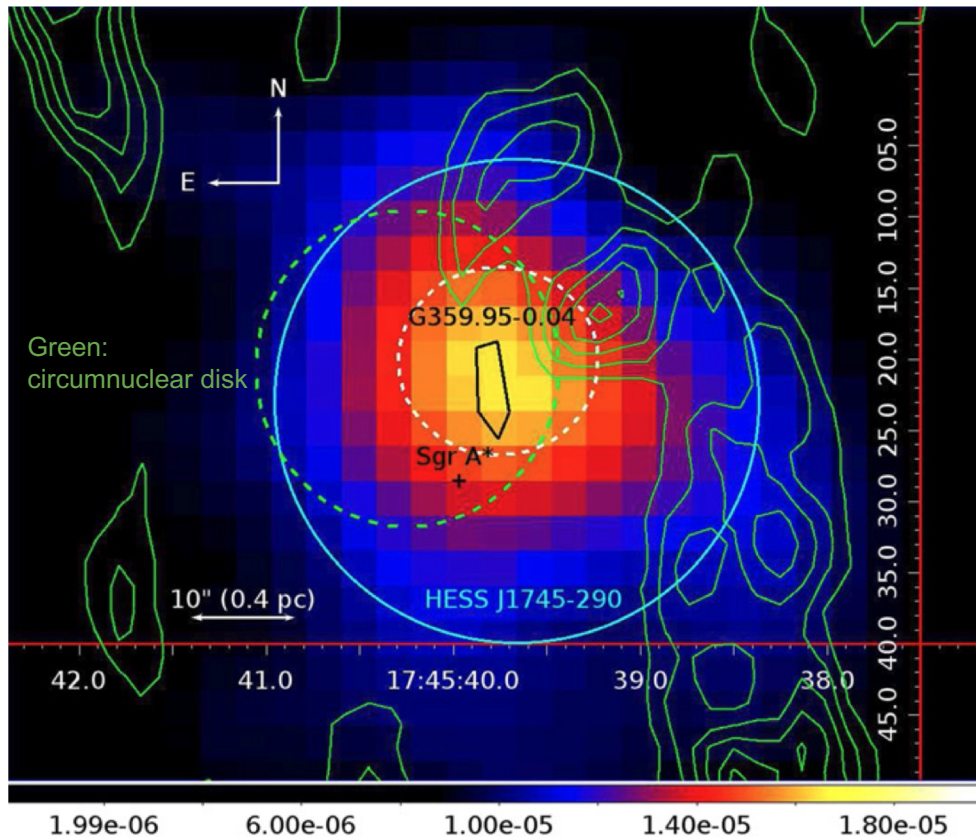

NuSTAR 20-40 keV image: the central few parsec

- 20-40 keV emission is centered around PWN G359.95-0.04

NuSTAR 20-40 keV (Mori+ 15)

Chandra 2-8 keV (Wang+ 16)

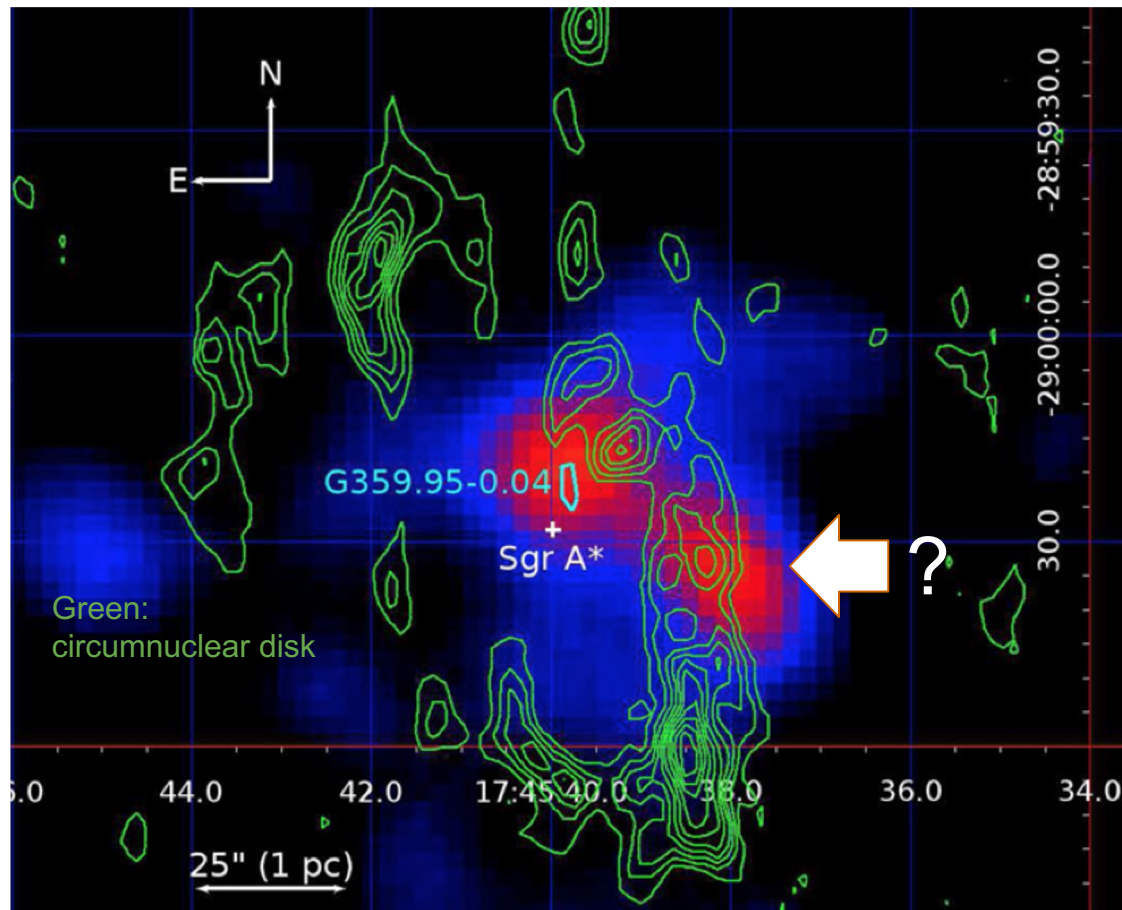

NuSTAR 40-79 keV image: the central few parsec

- 1) PWN G359.95-0.04
- 2) Unidentified hard X-ray source with no particular counterparts

PWN G359.95-0.04 = HESS J1745-290?

- G359.95-0.04 is the prominent hard X-ray source in the central pc.
- Sgr A* emit X-ray flares otherwise its quiescent X-ray emission is faint.
- Consistent PWN parameters (age $\sim 10^4$ yr) with Hinton & Aharonian 07

Figure 12. One-zone PWN model fit to the broad-band SED data including the 6 cm radio flux upper limit (blue arrow), G359.95-0.04 X-ray spectrum (green) and 0.1-10 TeV HESS spectrum of HESS J1745-290 (red).

Multi-wavelength SED fit with one-zone PWN evolution model (Mori+ 15)

Broken power-law model: $p_1 = 1.8$, $p_2 = 2.0$,
 $E_{\text{break}} = 50$ TeV, $E_{\text{min}} = 0.5$ TeV, $E_{\text{max}} = 200$ TeV

HEX-P: future X-ray probe mission in the 2030s

X-ray astrophysics landscape in the 2030s

- NASA's decadal survey => X-ray probe mission (\$1B budget)
- Project timeline
 - Proposal submission for phase A study: October 2023
 - Selection for phase A study: early 2024
 - Final selection in 2025
 - Launch in early 2030s

0.1-80 keV

0.2-30 keV
(non-focusing)

0.2-2 keV

< 1.5 keV

0.2-10 keV

HEX-P: next-generation all-purpose X-ray telescope

- Super XMM + NuSTAR telescope
- Energy range: 0.1 - 80 keV
- One LET (0.1-20 keV): 4" angular resolution (HPD)
- Two HET telescopes (2-80 keV): 15-25" angular resolution (HPD)
- 25 HEX-P posters at the HEAD meeting.
- **HEX-P will be uniquely suited for studying non-thermal X-ray sources and extreme particle accelerators.**

Cas A

Summary

- Many thanks to collaborators from NuSTAR, VERITAS, HAWC etc.
- NuSTAR detected non-thermal emission from numerous X-ray sources, including Galactic TeV sources
- NuSTAR measured photon indices varying between...
 - different source types: $\Gamma \sim 0$ (Jupiter, magnetars), $\Gamma \sim 1.5$ (pulsars), $\Gamma \sim 2-2.5$ (PWNe, filaments, and many), $\Gamma \sim 3$ (Cas A)
 - different regions: synchrotron burnoff
 - different times: Cas A hard X-ray knots
- Multi-wavelength SED and morphology studies are very important.
- Multi-messenger astrophysics for extreme accelerators in the 2030s
 - Synergy with other telescopes: COSI, CTA, ICECUBE, LHAASO, HAWC...
 - Particle acceleration, propagation + cooling => Morphology (x, y), time evolution (t) and photon energy (E).
 - Multi-zone, time-dependent SED modeling etc.
- Comments, suggestions, collaboration? Email: kaya@astro.columbia.edu
